Set administrator privileges Additionally, you can set up the app to require administrator privileges to mount an image, which is useful especially on Windows Vista and 7. I'm trying to figure out a way to switch between languages on my old laptop. I have a Y-drive, a Z-drive, and an X-drive. The Z-drive and X-drive are just extra USB ports. The Y-drive, however, contains a very small drive with a language dictionary that I need to switch to (it's a Polish dictionary). I've looked at my X-drive and it contains a file that was used for the other language. Is this the Y-drive? How do I tell? What is the difference between these drives?

Q: Retrieving database objects from web service I have a lot of data that is stored in a SQL Server database and I am going to use that same data for a website. I would like to have a webservice that will retrieve this data for me. I would like to use the classes that are generated by Entity Framework to store this data, and then I would need a webservice that would use the classes to generate JSON from the database. How can I go about this? Can I use EF classes to store data in a database and still use a webservice to return the data? Thanks.

A: This is a broad question and I'll try to answer broadly and specifically. What your asking is to abstract SQL Server and call it through web service. You can use EF to create a datacontext to talk to SQL Server. This would be available to you in any of your ASP.NET app, and it would be accessible from your web services. You are then trying to translate the data your database provides, to something your server has to store. The only way I can see to do this is to convert it to a database independent format (eg xml). You then wrap it in JSON. Your looking for a ORM that will map the database to your model. You need to ask yourself, is it worth the maintenance of this. Is there a business or project constraint.

Eg : I have an existing application and this requires legacy code to be used as is. I need a reliable and quick way of loading data into the app. If you can invest time and effort into re-architecting your app. You can try this : If you're using .NET 4 and above (and have used EF) then this may be the answer. I don't know what you're working with or what you mean by
